

In my code, Game has a method called `getValidBuildFields(Field field)` that, as you expect, returns a list of valid fields that can be built by a Worker on the provided Field.

Initially, I put this in Grid because I felt that it was Grid's responsibility for managing the board Fields and determining which ones are neighboring. However, I realized that which Fields a Worker can move to is actually based on the rules of the game and could change in variations of the game, and so I moved this method to the Game class.

In an interactive version of Santorini, I would prompt the user to select one of the Fields from `getValidBuildFields(field)` to have a given Worker on Field field extend the tower of. Once they select a field, we can get the Tower of the selected Field (using `getTower()`), and then build upon that tower (`getTower().build()`). Build does not take any arguments because building on a tower of heights 0-2 means placing a block, and building on a tower of height 3 means placing a dome.

Game determines whether a Tower on a Field can be built by checking:

1. Is it adjacent to the given Worker's Field's Position (use `getField().getPosition()` and compare `getX()` and `getY()` coordinates)?
2. Does it have a dome (use `getField().getTower().hasDome()`)?
3. Is it already occupied by another Worker (use `getFields().isOccupied()`)?

I delegated building upon a Tower to Worker because I felt that it was Worker's responsibility to move and build. However, when it comes to what is legal to build, I left that up to Game because it is Game's responsibility to determine what is legal.

One possible concern in my code for future updates is that I currently set a constant to track the maximum number of levels allowed in the Tower class. This constant determines whether a Tower has a dome or not. Of course, the rules of the game dictate that the maximum number of levels (including a Dome) is 4 (or 3 not counting Dome), not necessarily the Tower itself. As a result, I may need to have Tower take in an argument in its constructor when building. However, for this implementation, I set the max height inside of the Tower because otherwise would have involved either having Game handle creating empty Towers and adding them to Field, or else passing through parameters down many levels, both of which seemed coupled, so I avoided this at the moment.
